

# 16-Bit, 500kHz, MicroPower Sampling ANALOG-TO-DIGITAL CONVERTER

Check for Samples: ADS8322

#### **FEATURES**

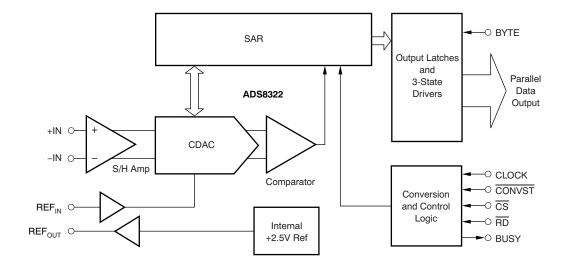

- HIGH-SPEED PARALLEL INTERFACE
- 500kHz SAMPLING RATE
- LOW POWER: 85mW at 500kHz
- INTERNAL 2.5V REFERENCE
- UNIPOLAR INPUT RANGE
- TQFP-32 PACKAGE

#### **APPLICATIONS**

- CT SCANNERS
- HIGH-SPEED DATA ACQUISITION
- TEST AND INSTRUMENTATION
- MEDICAL EQUIPMENT

# **DESCRIPTION**

The ADS8322 is a 16-bit, 500kHz analog-to-digital (A/D) converter with an internal 2.5V reference. The device includes a 16-bit capacitor-based successive approximation register (SAR) A/D converter with inherent sample-and-hold. The ADS8322 offers a full 16-bit interface, or an 8-bit option where data are read using two read cycles and eight pins. The ADS8322 is available in a TQFP-32 package and is ensured over the industrial -40°C to +85°C temperature range.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

All trademarks are the property of their respective owners.

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

Shaded cells indicate different specifications from ADS8322Y.

(6) Can vary ±30%.

Ideal input span; does not include gain or offset error.

 <sup>(3)</sup> LSB means least significant bit, with V<sub>REF</sub> equal to +2.5V; 1LSB = 76μV.
(4) Measured relative to an ideal, full-scale input [+In – (–In)] of 4.9999V. Thus, gain error includes the error of the internal voltage

Calculated on the first nine harmonics of the input frequency.

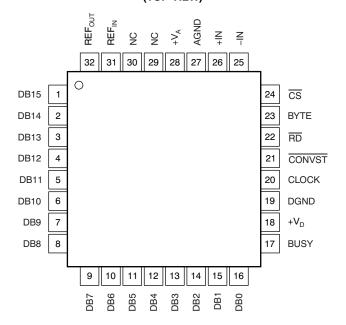

# ELECTRICAL CHARACTERISTICS: $+V_A = +5V$ (continued)

At  $-40^{\circ}$ C to  $+85^{\circ}$ C,  $+V_A = +5V$ ,  $V_{REF} = +2.5V$ ,  $f_{SAMPLE} = 500$ kHz, and  $f_{CLK} = 20 \bullet f_{SAMPLE}$ , unless otherwise specified.

#### THEORY OF OPERATION

The ADS8322 is a high-speed successive approximation register (SAR) A/D converter with an internal 2.5V bandgap reference. The architecture is based on capacitive redistribution, which inherently includes a sample-and-hold function. The basic operating circuit for the ADS8322 is shown in Figure 13.

The ADS8322 requires an external clock to run the conversion process. The clock can be run continuously or it can be gated to conserve power between conversions. This clock can vary between 25kHz (1.25kHz throughput) and 10MHz (500kHz throughput). The duty cycle of the clock is unimportant as long as the minimum HIGH and LOW

times are at least 40ns and the clock period is at least 100ns. The minimum clock frequency is governed by the parasitic leakage of the capacitive digital-to-analog (CDAC) capacitors internal to the ADS8322.

The analog input is provided to two input pins, +IN and -IN. When a conversion is initiated, the differential input on these pins is sampled on the internal capacitor array. While a conversion is in progress, both inputs are disconnected from any internal function.

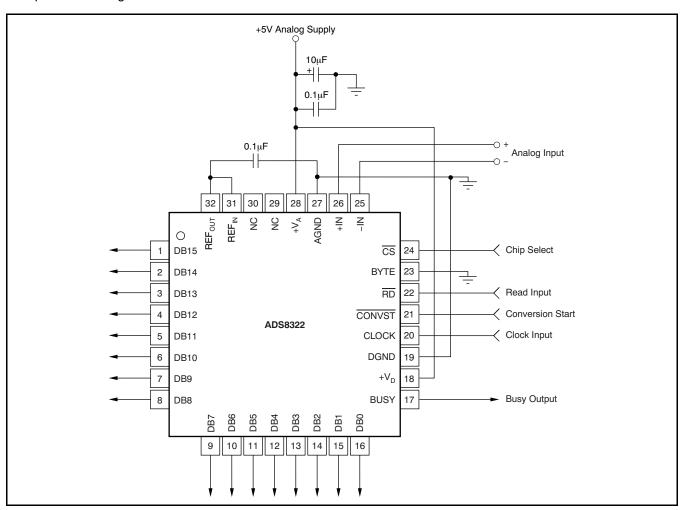

Figure 13. Typical Circuit Configuration

#### REFERENCE

Under normal operation, the  $REF_{OUT}$  pin should be directly connected to the  $REF_{IN}$  pin to provide an internal +2.5V reference to the ADS8322. The ADS8322 can operate, however, with an external reference in the range of 1.5V to 2.6V for a corresponding full-scale range of 3.0V to 5.2V.

The internal reference of the ADS8322 is double-buffered. If the internal reference is used to drive an external load, a buffer is provided between the reference and the load applied to the REF\_OUT pin (the internal reference can typically source and sink  $10\mu A$  of current). If an external reference is used, the second buffer provides isolation between the external reference and the CDAC. This buffer is also used to recharge all of the CDAC capacitors during conversion.

#### **ANALOG INPUT**

When the converter enters the Hold mode, the voltage difference between the +IN and -IN inputs is captured on the internal capacitor array. The voltage on the -IN input is limited between -0.1V and 0.5V, allowing the input to reject small signals which are common to both the +IN and -IN inputs. The +IN input has a range of -0.1V to +V<sub>A</sub> + 0.1V.

The input current on the analog inputs depends upon a number of factors: sample rate, input voltage, and source impedance. Essentially, the current into the ADS8322 charges the internal capacitor array during the sample period. After this capacitance has been fully charged, there is no further input current. The source of the analog input voltage must be able to charge the input capacitance (25pF) to a 16-bit settling level within the acquisition time (400ns) of the device. When the converter goes into Hold mode, the input impedance is greater than  $1G\Omega$ .

Care must be taken regarding the absolute analog input voltage. To maintain the linearity of the converter, the –IN input should not drop below GND – 100mV or exceed GND + 0.5V. The +IN input should always remain within the range of GND – 100mV to  $V_A$  + 100mV. Outside of these ranges, the converter linearity may not meet specifications. To minimize noise, low-bandwidth input signals with low-pass filters should be used.

#### **DIGITAL INTERFACE**

#### **TIMING AND CONTROL**

See the timing diagram and the *Timing Characteristics* section for detailed information on timing signals and the respective requirements for each.

The ADS8322 uses an external clock (CLOCK) which controls the conversion rate of the CDAC. With a 10MHz external clock, the A/D converter sampling rate is 500kHz, which corresponds to a 2µs maximum throughput time.

Conversions are initiated by bringing the CONVST pin low for a minimum of 20ns (after the 20ns minimum requirement has been met, the CONVST pin can be brought high), while CS is low. The ADS8322 switches from Sample-to-Hold mode on the falling edge of the CONVST command. Following the first rising edge of the external clock after a CONVST low, the ADS8322 begins conversion (this first rising edge of the external clock represents the start of clock cycle one; the ADS8322 requires 16 rising clock edges to complete a conversion). The BUSY output goes high immediately following CONVST going low. BUSY stays high through the conversion process and returns low when the conversion has ended.

Both  $\overline{RD}$  and  $\overline{CS}$  can be high during and before a conversion (although  $\overline{CS}$  must be low when  $\overline{CONVST}$  goes low to initiate a conversion). Both the  $\overline{RD}$  and  $\overline{CS}$  pins are brought low in order to enable the parallel output bus with the conversion.

#### **READING DATA**

The ADS8322 outputs full parallel data in Straight Binary format, as shown in Table 1. The parallel output is active when CS and RD are both LOW. The output data should not be read 125ns before the falling edge of CONVST and 10ns after the falling edge. Any other combination of CS and RD will 3-state the parallel output. Refer to Table 1 for ideal output codes.

#### **BYTE**

The output data appear as a full 16-bit word on DB15- DB0 (MSB-LSB), if BYTE is low. The result may also be read on an 8-bit bus by using only DB7-DB0. In this case two reads are necessary. The first read proceeds as before, leaving BYTE low and reading the eight least significant bits on DB7-DB0, then bringing BYTE high. When BYTE is high, the upper eight bits (D15-D8) appear on DB7-DB0.

### **NOISE**

Figure 14 shows the transition noise of the ADS8322. A low-level dc input was applied to the analog input pins and the converter was put through 8,192 conversions. The digital output of the A/D converter varies in output code due to the internal noise of the ADS8322. This characteristic is true for all 16-bit SAR-type A/D converters. Using a histogram to plot the output codes, the distribution should appear bell-shaped, with the peak of the bell curve representing the nominal code for the input value. The  $\pm 1\sigma$ ,  $\pm 2\sigma$ , and  $\pm 3\sigma$  distributions respectively represent the 68.3%, 95.5%, and 99.7% of all codes. The transition noise can be calculated by dividing the number of codes measured by six; this yields the ±3σ distribution, or 99.7%, of all codes. Statistically, up to three codes could fall outside the distribution when executing 1,000 conversions. The ADS8322, with five output codes for the  $\pm 3\sigma$  distribution, yields a < ±0.8LSB transition noise at 5V operation. Remember that to achieve this low-noise performance, the peak-to-peak noise of the input signal and reference must be  $< 50\mu V$ .

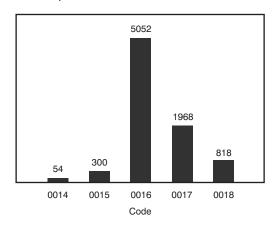

Figure 14. Histogram of 8,192 Conversions of a Low-Level DC Input

#### **AVERAGING**

The noise of the A/D converter can be compensated by averaging the digital codes. By averaging conversion results, transition noise is reduced by a factor of  $1/\sqrt{n}$ , where *n* is the number of averages. For example, averaging four conversion results reduces the transition noise by 1/2 to  $\pm 0.25$  LSBs. Averaging should only be used for input signals with frequencies near dc.

For ac signals, a digital filter can be used to low-pass filter and decimate the output codes. configuration works in a similar manner to averaging: for every decimation by 2, the signal-to-noise ratio improves by 3dB.

#### **LAYOUT**

For optimum performance, care should be taken with the physical layout of the ADS8322 circuitry. This consideration is particularly true if the CLOCK input is approaching the maximum throughput rate.

As the ADS8322 offers single-supply operation, it is often used in close proximity with digital logic, microcontrollers, microprocessors, and digital signal processors. The more digital logic present in the design and the higher the switching speed, the more difficult it is to achieve good performance from the converter.

The basic SAR architecture is sensitive to glitches or sudden changes on the power supply, reference, ground connections and digital inputs that occur just before latching the output of the analog comparator. Thus, during any single conversion for an n-bit SAR converter, there are n windows in which large external transient voltages can affect the conversion result. Such alitches might originate from switching power supplies, or nearby digital logic or high-power devices.

The degree of error in the digital output depends on the reference voltage, layout, and the exact timing of the external event. These errors can change if the external event changes in time with respect to the CLOCK input.

On average, the ADS8322 draws very little current from an external reference, as the reference voltage is internally buffered. If the reference voltage is external and originates from an op amp, make sure that it can drive the bypass capacitor or capacitors without oscillation.

The AGND and DGND pins should be connected to a clean ground point. In all cases, this point should be the *analog* ground. Avoid connections which are too close to the grounding point of a microcontroller or digital signal processor. If required, run a ground trace directly from the converter to the power supply entry point. The ideal layout will include an analog ground plane dedicated to the converter and associated analog circuitry.

As with the GND connections,  $V_{DD}$  should be connected to a +5V power supply plane, or trace, that is separate from the connection for digital logic until they are connected at the power entry point. Power to the ADS8322 should be clean and well-bypassed. A 0.1µF ceramic bypass capacitor should be placed as close to the device as possible. In addition, a 1µF to 10µF capacitor is recommended. If needed, an even larger capacitor and a 5 $\Omega$  or 10 $\Omega$  series resistor may be used to low-pass filter a noisy supply. In some situations, additional bypassing may be required, such as a 100µF electrolytic capacitor, or even a Pi filter made up of inductors and capacitors—all designed to essentially low-pass filter the +5V supply, removing the high-frequency noise.

#### **REVISION HISTORY**

NOTE: Page numbers for previous revisions may differ from page numbers in the current version.

| C | hanges from Original (July, 2001) to Revision A                             | Page |
|---|---|------|
| • | Updated document format to current standards                                | 1    |
| • | Deleted lead temperature specifications from Absolute Maximum Ratings table | 2    |
| • | Changed acquisition time specification from .4µs (max) to 350ns (min)       | 3    |
| • | Changed acquisition time specification from .4µs (max) to 350ns (min)       | 6    |
| • | Added Figure 12, Linearity Error and Differential Linearity Error vs Code   | 8    |

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

(2) RoHS: TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

**Green:** TI defines "Green" to mean the content of Chlorine (CI) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

- (3) MSL, Peak Temp. The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.
- (4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.
- (5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.
- (6) Lead finish/Ball material Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.

**Important Information and Disclaimer:** The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

# PBS (S-PQFP-G32)

# PLASTIC QUAD FLATPACK

NOTES:

- A. All linear dimensions are in millimeters.
- B. This drawing is subject to change without notice.
- C. Publication IPC-7351 is recommended for alternate designs.
- D. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Refer to IPC 7525 for stencil design considerations.
- E. Customers should contact their board fabrication site for recommended solder mask tolerances between and around signal pads.
