

ADS7044 超低功耗、超小尺寸、12 位、1MSPS、SAR ADC

1 特性

- 业界第一款具有毫微瓦功耗的逐次逼近寄存器 (SAR) 模数转换器 (ADC):
 - 1MSPS 和 1.8V AVDD 时为 261 μ W
 - 1MSPS 和 3V AVDD 时为 900 μ W
 - 100kSPS 和 3V AVDD 时为 90 μ W
 - 1kSPS 和 3V AVDD 时低于 1 μ W
- 业界最小的 SAR ADC:
 - 采用 X2QFN-8 封装, 封装尺寸为 2.25mm²
- 1MSPS 吞吐量且零延迟
- 宽工作范围:
 - AVDD: 1.65V 至 3.6V
 - DVDD: 1.65V 至 3.6V (与 AVDD 无关)
 - 温度范围: -40°C 至 125°C
- 出色的性能:
 - 12 位分辨率且无丢码 (NMC)
 - 最大 ± 1 最低有效位 (LSB) 的差分非线性 (DNL) 和积分非线性 (INL)
 - 71dB 的信噪比 (SNR) (3V AVDD 时)
 - 85dB 的总谐波失真 (SNR) (3V AVDD 时)
- 单极差分输入范围:
 - AVDD 至 AVDD
- 集成偏移校准
- 串行外设接口 (SPI)[™]- 兼容串口: 16MHz
- 符合 JESD8-7A 标准的数字 I/O

2 应用

- 低功耗数据采集
- 电池供电类手持设备
- 液位传感器
- 超声波流量计
- 电机控制
- 可穿戴健身器
- 便携式医疗设备
- 硬盘
- 血糖仪

3 说明

ADS7044 是一款 1MSPS 模数转换器 (ADC)。该器件支持较宽的模拟输入电压范围 ($\pm 1.65V$ 至 $\pm 3.6V$)，并且包括一个基于电容且内置采样保持电路的逐次逼近寄存器 (SAR) ADC。串行外设接口 (SPI) 兼容串口由 $\overline{CS}$ 和 SCLK 信号控制。输入信号在 $\overline{CS}$ 下降沿进行采样，SCLK 用于转换和串行数据输出。此器件支持宽范围的数字电源 (1.65V 至 3.6V)，可直接连接到各类主机控制器。此器件符合 JESD8-7A 标准的标称 DVDD 范围 (1.65V 至 1.95V)。

此器件采用 8 引脚微型引线 X2QFN 封装，额定工作温度范围为 -40°C 至 125°C。此器件尺寸微小且功耗极低，非常适合空间受限类电池供电应用。

器件信息⁽¹⁾

部件名称	封装	封装尺寸 (标称值)
ADS7044	X2QFN (8)	1.50mm x 1.50mm
	超薄小外形尺寸封装 (VSSOP)(8)	2.30mm x 2.00mm

(1) 要了解所有可用封装，请见数据表末尾的可订购产品附录。

典型应用

注：此器件比 0805 (2012 公制) SMD 元件小。

4 修订历史记录

Changes from Revision C (February 2015) to Revision D	Page
• Changed Figure 1	8
• Changed <i>Serial Interface</i> section: changed last half of first paragraph, changed Figure 35	19
• Changed Figure 38	22
• 添加了社区资源部分	31

Changes from Revision B (December 2014) to Revision C	Page
• 已更改宽工作电压范围 特性 要点: 已将 AVDD 的值从 1.8V 改为 1.65V	1
• 已将宽模拟输入电压范围下限值改为 $\pm 1.65V$ (说明 部分第一段)	1
• Changed AVDD parameter minimum specification in <i>Recommended Operating Conditions</i> table	5
• Changed E_O parameter uncalibrated test conditions in <i>Electrical Characteristics</i> table	6
• Changed <i>Maximum throughput rate</i> parameter test conditions in <i>Electrical Characteristics</i> table	6
• Changed AVDD parameter minimum specification in <i>Electrical Characteristics</i> table	7
• Changed conditions for <i>Timing Characteristics</i> table: changed range of AVDD and added C_{LOAD} condition	7
• Changed t_{D_CKDO} specification in <i>Timing Characteristics</i> table	7
• Added f_{SCLK} minimum specification to <i>Timing Characteristics</i> table	7
• Changed titles of Figure 26 to Figure 30	12
• Changed <i>Reference</i> sub-section in <i>Feature Description</i> section	16
• Changed AVDD range in description of $f_{CLK-CAL}$ parameter in Table 2	21
• Changed AVDD range in description of $f_{CLK-CAL}$ parameter in Table 3	22
• Changed <i>Reference Circuit</i> section in <i>Application Information</i>	25
• Added last two sentences to <i>AVDD and DVDD Supply Recommendations</i> section	29

Changes from Revision A (November 2014) to Revision B	Page
• Changed ESD Ratings table to latest standards	5
• Added footnote 3 to <i>Electrical Characteristics</i> table	6
• Changed y-axis unit in Figure 30	13

Changes from Original (November 2014) to Revision A	Page
• 已更改产品预览数据表.....	1

5 Pin Configuration and Functions

Pin Functions

NAME	PIN NO.		I/O	DESCRIPTION
	RUG	DCU		
AINM	8	5	Analog input	Analog signal input, negative
AINP	7	6	Analog input	Analog signal input, positive
AVDD	6	7	Supply	Analog power-supply input, also provides the reference voltage to the ADC
$\overline{\text{CS}}$	1	4	Digital input	Chip-select signal, active low
DVDD	4	1	Supply	Digital I/O supply voltage
GND	5	8	Supply	Ground for power supply, all analog and digital signals are referred to this pin
SCLK	3	2	Digital input	Serial clock
SDO	2	3	Digital output	Serial data out

6 Specifications

6.1 Absolute Maximum Ratings⁽¹⁾

	MIN	MAX	UNIT
AVDD to GND	−0.3	3.9	V
DVDD to GND	−0.3	3.9	V
AINP to GND	−0.3	AVDD + 0.3	V
AINM to GND	−0.3	AVDD + 0.3	V
Digital input voltage to GND	−0.3	DVDD + 0.3	V
Storage temperature, T _{stg}	−60	150	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, which do not imply functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions*. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

6.2 ESD Ratings

		VALUE	UNIT
V _(ESD) Electrostatic discharge	Human body model (HBM), per ANSI/ESDA/JEDEC JS-001 ⁽¹⁾	±2000	V
	Charged device model (CDM), per JEDEC specification JESD22-C101 ⁽²⁾	±1000	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process.

- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process.

6.3 Recommended Operating Conditions

over operating free-air temperature range (unless otherwise noted)

	MIN	MAX	UNIT
AVDD Analog supply voltage range	1.65	3.6	V
DVDD Digital supply voltage range	1.65	3.6	V
T _A Operating free-air temperature	−40	125	°C

6.4 Thermal Information

THERMAL METRIC ⁽¹⁾		ADS7044		UNIT
		RUG (X2QFN)	DCU (VSSOP)	
		8 PINS	8 PINS	
R _{θJA}	Junction-to-ambient thermal resistance	177.5	235.8	°C/W
R _{θJC(top)}	Junction-to-case (top) thermal resistance	51.5	79.8	°C/W
R _{θJB}	Junction-to-board thermal resistance	76.7	117.6	°C/W
Ψ _{JT}	Junction-to-top characterization parameter	1.0	8.9	°C/W
Ψ _{JB}	Junction-to-board characterization parameter	76.7	116.5	°C/W
R _{θJC(bot)}	Junction-to-case (bottom) thermal resistance	N/A	N/A	°C/W

- (1) For more information about traditional and new thermal metrics, see the *IC Package Thermal Metrics* application report, [SPRA953](#).

6.5 Electrical Characteristics

At $T_A = -40^\circ\text{C}$ to 125°C , $AVDD = 3\text{ V}$, $DVDD = 1.65\text{ V}$ to 3.6 V , $f_{\text{SAMPLE}} = 1\text{ MSPS}$, unless otherwise noted.

7 Parameter Measurement Information

7.1 Digital Voltage Levels

The device complies with the JESD8-7A standard for DVDD from 1.65 V to 1.95 V. Figure 31 shows voltage levels for the digital input and output pins.

Figure 31. Digital Voltage Levels as per the JESD8-7A Standard

8 Detailed Description

8.1 Overview

The ADS7044 is an ultralow-power, ultra-small analog-to-digital converter (ADC) that supports a wide analog input range. The analog input range for the device is defined by the AVDD supply voltage. The device samples the input voltage across the AINP and AINM pins on the $\overline{CS}$ falling edge and starts the conversion. The clock provided on the SCLK pin is used for conversion and data transfer. During conversions, both the AINP and AINM pins are disconnected from the sampling circuit. After the conversion completes, the sampling capacitors are reconnected across the AINP and AINM pins and the device enters acquisition phase.

The device has an internal offset calibration. The offset calibration can be initiated by the user either on power-up or during normal operation; see the [Offset Calibration](#) section for more details.

The device also provides a simple serial interface to the host controller and operates over a wide range of digital power supplies. The device requires only a 16-MHz SCLK for supporting a throughput of 1 MSPS. The digital interface also complies with the JESD8-7A (normal range) standard. The [Functional Block Diagram](#) section provides a block diagram of the device.

8.2 Functional Block Diagram

8.3 Feature Description

8.3.1 Reference

The device uses the analog supply voltage (AVDD) as a reference, as shown in [Figure 32](#). TI recommends decoupling the AVDD pin with a 1- μ F, low equivalent series resistance (ESR) ceramic capacitor. The minimum capacitor value required for AVDD is 200 nF. The AVDD pin functions as a switched capacitor load to the source powering AVDD. The decoupling capacitor provides the instantaneous charge required by the internal circuit and helps in maintaining a stable dc voltage on the AVDD pin. TI recommends powering the AVDD pin with a low output impedance and low-noise regulator (such as the [TPS79101](#)).

Figure 32. Reference for the Device

Feature Description (continued)

8.3.2 Analog Input

The device supports differential analog inputs. The ADC samples the difference between AINP and AINM and converts for this voltage. The device is capable of accepting a signal from 0 V to AVDD on the AINM input and a signal from 0 V to AVDD on the AINP input. Figure 33 represents the equivalent analog input circuits for the sampling stage. The device has a low-pass filter followed by the sampling switch and sampling capacitor. The sampling switch is represented by an R_s (typically 50 Ω) resistor in series with an ideal switch and C_s (typically 15 pF) is the sampling capacitor. The ESD diodes are connected from both analog inputs to AVDD and ground.

Figure 33. Equivalent Input Circuit for the Sampling Stage

The analog input full-scale range (FSR) is defined by the reference voltage of the ADC. The relationship between the FSR and the reference voltage can be determined by: $FSR = 2 \times V_{REF} = 2 \times AVDD$.

8.3.3 ADC Transfer Function

The device output is in twos complement format. The device resolution can be computed by Equation 1:

$$1 \text{ LSB} = FSR / 2^N$$

where:

- $FSR = 2 \times V_{REF} = 2 \times AVDD$ and
- $N = 12$

(1)

Feature Description (continued)

Figure 34 and Table 1 show the ideal transfer characteristics for the device.

Figure 34. Ideal Transfer Characteristics

Table 1. Transfer Characteristics

INPUT VOLTAGE (AINP-AINM)	CODE	DESCRIPTION	IDEAL OUTPUT CODE
$\leq -(V_{REF} - 1 \text{ LSB})$	NFSC	Negative full-scale code	800
$-(V_{REF} - 1 \text{ LSB})$ to $-(V_{REF} - 2 \text{ LSBs})$	NFSC + 1	—	801
0 to 1 LSB	MC	Mid code	000
1 LSB to 2 LSBs	MC + 1	—	001
$\geq V_{REF} - 1 \text{ LSB}$	PFSC	Positive full-scale code	7FF

8.3.4 Serial Interface

The device supports a simple, SPI-compatible interface to the external host. The $\overline{\text{CS}}$ signal defines one conversion and serial transfer frame. A frame starts with a $\overline{\text{CS}}$ falling edge and ends with a $\overline{\text{CS}}$ rising edge. The SDO pin outputs the ADC conversion results. Figure 35 shows a detailed timing diagram for the serial interface. A minimum delay of $t_{\text{SU_CSCK}}$ must elapse between the $\overline{\text{CS}}$ falling edge and the first SCLK falling edge. The device uses the clock provided on the SCLK pin for conversion and data transfer. The conversion result is available on the SDO pin with the first two bits set to 0, followed by 12 bits of the conversion result. The first zero is launched on the SDO pin on the $\overline{\text{CS}}$ falling edge. Subsequent bits (starting with another 0 followed by the conversion result) are launched on the SDO pin on subsequent SCLK falling edges. The SDO output remains low after 14 SCLKs. A $\overline{\text{CS}}$ rising edge ends the frame and brings the serial data bus to 3-state. For the acquisition of the next sample, a minimum time of t_{ACQ} must be provided after the conversion of the current sample is completed. For details on timing specifications, see the [Timing Characteristics](#) table.

The device initiates offset calibration on first $\overline{\text{CS}}$ falling edge after power-up and the SDO output remains low during the first serial transfer frame after power-up. For details, refer to the [Offset Calibration](#) section.

Figure 35. Serial Interface Timing Diagram

8.4 Device Functional Modes

8.4.1 Offset Calibration

The device includes a feature to calibrate its internal offset. The device initiates offset calibration on the first $\overline{\text{CS}}$ falling edge after power up and during offset calibration, the analog input pins (AINP and AINM) are disconnected from the sampling stage. After the first serial transfer frame, the device starts operating with either uncalibrated or calibrated offset, depending on the number of SCLKs provided in the first serial transfer frame. Offset calibration can also be initiated by the user during normal operation. Figure 36 shows the offset calibration process. The SDO output remains low during the first serial transfer frame.

The device includes an internal offset calibration register (OCR) that stores the offset calibration result. The OCR is an internal register and cannot be accessed by the user through the serial interface. The OCR is reset to zero on power-up. Therefore, TI recommends calibrating the offset on power-up to bring the offset within the specified limits. If there is a significant change in operating temperature or analog supply voltage, the offset can be recalibrated during normal operation.

- (1) See the [Timing Characteristics](#) section for timing specifications.
- (2) See the [Offset Calibration During Normal Operation](#) section for details.
- (3) See the [Offset Calibration on Power-Up](#) section for details.
- (4) The power recycle on the AVDD supply is required to reset the offset calibration and to bring the device to a power-up state.

Figure 36. Offset Calibration

Device Functional Modes (continued)

8.4.1.1 Offset Calibration on Power-Up

The device starts offset calibration on the first $\overline{\text{CS}}$ falling edge after power-up and calibration completes if the $\overline{\text{CS}}$ pin remains low for at least 16 SCLKs after the first $\overline{\text{CS}}$ falling edge. The SDO output remains low during calibration. The minimum acquisition time must be provided after calibration for acquiring the first sample. If the device is not provided with at least 16 SCLKs during the first serial transfer frame after power-up, the OCR is not updated. Table 2 provides the timing parameters for offset calibration on power-up.

For subsequent samples, the device adjusts the conversion results with the value stored in the OCR. The conversion result adjusted with the value stored in OCR is provided by the device on the SDO output. Figure 37 shows the timing diagram for offset calibration on power-up.

Table 2. Offset Calibration on Power-Up

		MIN	TYP	MAX	UNIT
$f_{\text{CLK-CAL}}$	SCLK frequency for calibration at $2.25\text{ V} < \text{AVDD} < 3.6\text{ V}$			16	MHz
$f_{\text{CLK-CAL}}$	SCLK frequency for calibration at $1.65\text{ V} < \text{AVDD} < 2.25\text{ V}$			12	MHz
$t_{\text{POWERUP-CAL}}$	Calibration time at power-up	16 t_{SCLK}			ns
t_{ACQ}	Acquisition time	200			ns
$t_{\text{PH-CS}}$	$\overline{\text{CS}}$ high time	t_{ACQ}			ns

Figure 37. Offset Calibration on Power-Up Timing Diagram

8.4.1.2 Offset Calibration During Normal Operation

The offset can also be calibrated during normal device operation. Offset calibration can be done during normal device operation if at least 32 SCLKs are provided in one serial transfer frame. During the first 14 SCLKs, the device converts the sample acquired on the $\overline{\text{CS}}$ falling edge and provides data on the SDO output. The device initiates the offset calibration on the 17th SCLK falling edge and calibration is completed on the 32nd SCLK falling edge. The SDO output remains low after the 14th SCLK falling edge and SDO goes to 3-state after $\overline{\text{CS}}$ goes high. If the device is provided with less than 32 SCLKs during a serial transfer frame, the OCR is not updated. Table 3 provides the timing parameters for offset calibration during normal operation.

For subsequent samples, the device adjusts the conversion results with the value stored in OCR. The conversion result adjusted with the value stored in the OCR is provided by the device on the SDO output. Figure 38 shows the timing diagram for offset calibration during normal operation.

Table 3. Offset Calibration During Normal Operation

9 Application and Implementation

NOTE

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

9.1 Application Information

The two primary circuits required to maximize the performance of a high-precision, successive approximation register (SAR), analog-to-digital converter (ADC) are the input driver and the reference driver circuits. This section details some general principles for designing the input driver circuit, reference driver circuit, and provides some application circuits designed for the ADS7044.

9.2 Typical Applications

9.2.1 Single-Supply DAQ with the ADS7044

Figure 39. DAQ Circuit: Single-Supply DAQ

9.2.1.1 Design Requirements

The goal of this application is to design a single-supply digital acquisition (DAQ) circuit based on the ADS7044 with SNR greater than 71 dB and THD less than -85 dB for a differential input signal having an amplitude of $AVDD$ with a common-mode voltage of $AVDD / 2$ and input frequencies of 5 kHz at a throughput of 1 MSPS.

9.2.1.2 Detailed Design Procedure

The input driver circuit for a high-precision ADC mainly consists of two parts: a driving amplifier and an antialiasing filter. Careful design of the front-end circuit is critical to meet the linearity and noise performance of a high-precision ADC.

Typical Applications (continued)

9.2.1.2.1 Antialiasing Filter

Converting analog-to-digital signals requires sampling an input signal at a rate greater than or equal to the Nyquist rate. Any higher frequency content in the input signal beyond half the sampling frequency is digitized and folded back into the low-frequency spectrum. This process is called *aliasing*. Therefore, an external, antialiasing filter must be used to remove the harmonic content from the input signal before being sampled by the ADC. An antialiasing filter is designed as a low-pass RC filter, for which the 3-dB bandwidth is optimized for noise, response time, and throughput. For dc signals with fast transients (including multiplexed input signals), a high-bandwidth filter is designed to allow the signal to be accurately set at the ADC inputs during the small acquisition time window. Figure 40 provides the equation for determining the bandwidth of antialiasing filter.

Figure 40. Antialiasing Filter

For ac signals, the filter bandwidth must be kept low to band limit the noise fed into the ADC input, thereby increasing the signal-to-noise ratio (SNR) of the system. Besides filtering the noise from the front-end drive circuitry, the RC filter also helps attenuate the sampling charge injection from the switched-capacitor input stage of the ADC. A filter capacitor, C_{FLT} , is connected across the ADC inputs. This capacitor helps reduce the sampling charge injection and provides a charge bucket to quickly charge the internal sample-and-hold capacitors during the acquisition process. As a rule of thumb, the value of this capacitor must be at least 20 times the specified value of the ADC sampling capacitance. For this device, the input sampling capacitance is equal to 15 pF. Thus, the value of C_{FLT} must be greater than 300 pF. The capacitor must be a COG- or NPO-type because these capacitor types have a high-Q, low-temperature coefficient, and stable electrical characteristics under varying voltages, frequency, and time.

Note that driving capacitive loads can degrade the phase margin of the input amplifiers, thus making the amplifier marginally unstable. To avoid amplifier stability issues, series isolation resistors (R_{FLT}) are used at the output of the amplifiers. A higher value of R_{FLT} is helpful from the amplifier stability perspective, but adds distortion as a result of interactions with the nonlinear input impedance of the ADC. Distortion increases with source impedance, input signal frequency, and input signal amplitude. Therefore, the selection of R_{FLT} requires balancing the stability and distortion of the design.

The input amplifier bandwidth must be much higher than the cutoff frequency of the antialiasing filter. TI strongly recommends performing a SPICE simulation to confirm that the amplifier has more than 40° phase margin with the selected filter. Simulation is critical because even with high-bandwidth amplifiers, some amplifiers may require more bandwidth than others to drive similar filters.

Typical Applications (continued)

9.2.1.2.2 Input Amplifier Selection

Selection criteria for the input amplifiers is highly dependent on the input signal type and the performance goals of the data acquisition system. Some key amplifier specifications to consider while selecting an appropriate amplifier to drive the inputs of the ADC are:

- **Small-signal bandwidth:** Select the small-signal bandwidth of the input amplifiers to be high enough to settle the input signal in the acquisition time of the ADC. Higher bandwidth reduces the closed-loop output impedance of the amplifier, thus allowing the amplifier to more easily drive the low cutoff frequency RC filter at the ADC inputs. Higher bandwidth also minimizes the harmonic distortion at higher input frequencies. In order to maintain the overall stability of the input driver circuit, select the amplifier bandwidth as described in [Equation 2](#):

$$GBW \geq 4 \times \frac{1}{2\pi \times 2R_{FLT} \times C_{FLT}}$$

where:

- GBW = Unity-gain bandwidth (2)
- **Noise:** Noise contribution of the front-end amplifiers must be low enough to prevent any degradation in SNR performance of the system. As a rule of thumb, to ensure that the noise performance of the data acquisition system is not limited by the front-end circuit, keep the total noise contribution from the front-end circuit below 20% of the input-referred noise of the ADC. Noise from the input driver circuit is band limited by designing a low cutoff frequency RC filter, as explained in [Equation 3](#).

$$\sqrt{\left(\frac{V_{1/f_AMP_PP}}{6.6 \times 2\beta}\right)^2 + \left[\frac{(2 \times e_{n_RMS})^2 + ((2 \times i_n \times \beta)^2 \times (R_2^2 + R_4^2)) + ((2 \times \sqrt{4kT} \times (1-\beta))^2 \times (R_1 + R_3))}{(2\beta)^2} + 4kT(R_2 + R_4)\right] \times \frac{\pi}{2} \times f_{-3dB}} \leq \frac{1}{5} \times \frac{V_{REF}}{\sqrt{2}} \times 10^{\left(\frac{SNR(dB)}{20}\right)}$$

where:

- V_{1/f_AMP_PP} is the peak-to-peak flicker noise in μV_{rms} ,
- e_{n_RMS} is the amplifier broadband noise,
- f_{-3dB} is the –3-dB bandwidth of the RC filter,
- k is the Boltzmann's constant, and
- T is absolute temperature in kelvin.
- For symmetrical feedback, $\beta = R1 / (R1 + R2) = R3 / (R3 + R4)$.
- For details on noise analysis, refer to the technical brief [Analysis of fully differential amplifiers \(SLYT157\)](#) (3)
- **Settling time:** For dc signals with fast transients that are common in a multiplexed application, the input signal must settle to the desired accuracy at the inputs of the ADC during the acquisition time window. This condition is critical to maintain the overall linearity performance of the ADC. Typically, the amplifier data sheets specify the output settling performance only up to 0.1% to 0.001%, which may not be sufficient for the desired accuracy. Therefore, always verify the settling behavior of the input driver with TINA™-SPICE simulations before selecting the amplifier.

The **OPA316** is selected for this application for its rail-to-rail input and output swing, low-noise (11 nV/ $\sqrt{Hz}$), and low-power (400 μA) performance to support a single-supply data acquisition circuit.

9.2.1.2.3 Reference Circuit

The analog supply voltage of the device is also used as a voltage reference for conversion. TI recommends decoupling the AVDD pin with a 1- μF , low-ESR ceramic capacitor. The minimum capacitor value required for AVDD is 200 nF.

For a step-by-step design procedure, circuit schematics, bill of materials, PCB files, simulation results, and test results, refer to [TI Precision Design TIPD168, Three 12-Bit Data Acquisition Reference Designs Optimized for Low Power and Ultra-Small Form Factor \(TIDU390\)](#).

9.2.1.3 Application Curve

Figure 41 shows the FFT plot for the device with a 5-kHz input frequency for the circuit in Figure 39.

SNR = 72.2 dB THD = -85.7 dB SINAD = 72 dB
Number of samples = 8192

Figure 41. Test Results for the ADS7044 and OPA316 for a 5-kHz Input

9.2.2 Ultra-Low Power and Ultra-Small, High CMRR DAQ Circuit with the ADS7044

Figure 42. ADS7044 DAQ Circuit

9.2.2.1 Design Requirements

For this design example, use the parameters listed in Table 4 as input parameters.

Table 4. Design Parameters

DESIGN PARAMETER	GOAL VALUE
SINAD	71 dB
Throughput	1 MSPS
AVDD	3.3 V
AVDD current consumption	800 μ A (at a 5-kHz f_{IN}) and 1500 μ A (at a 25-kHz f_{IN})
V_{IN} to the THS4531A	–AVDD to AVDD
Common-mode voltage for V_{IN} to the THS4531A	0 V to AVDD / 2

9.2.2.2 Detailed Design Procedure

See the [Detailed Design Procedure](#) section in the [Single-Supply DAQ with the ADS7044](#) application for further details.

To achieve a SINAD of 71 dB, the operational amplifier must have high bandwidth to settle the input signal within the acquisition time of the ADC. The operational amplifier must have low noise to keep the total system noise below 20% of the input-referred noise of the ADC.

For the application circuit shown in Figure 42, the THS4531A is selected for its high bandwidth (36 MHz), low noise (10 nV/ $\sqrt{\text{Hz}}$), and for its capability to set the common-mode voltage for the ADC. The THS4531A rejects the variation of common-mode at its input and provides a CMRR of 90 dB (min).

9.2.2.3 Application Curves

Figure 43 shows the FFT plot for the device with a 5-kHz input frequency for the circuit in Figure 42. Figure 44 shows the FFT plot for the device with a 25-kHz input frequency for the circuit in Figure 42.

10 Power-Supply Recommendations

10.1 AVDD and DVDD Supply Recommendations

The device has two separate power supplies: AVDD and DVDD. The device operates on AVDD; DVDD is used for the interface circuits. AVDD and DVDD can be independently set to any value within the permissible ranges. The AVDD supply also defines the full-scale input range of the device. Decouple the AVDD and DVDD pins individually with 1-μF ceramic decoupling capacitors, as shown in Figure 45. The minimum capacitor value required for AVDD and DVDD is 200 nF and 20 nF, respectively. If both supplies are powered from the same source, a minimum capacitor value of 220 nF is required for decoupling.

Figure 45. Power-Supply Decoupling

10.2 Estimating Digital Power Consumption

The current consumption from the DVDD supply depends on the DVDD voltage, load capacitance on the SDO line, and the output code. The load capacitance on the SDO line is charged by the current from the SDO pin on every rising edge of the data output and is discharged on every falling edge of the data output. The current consumed by the device from the DVDD supply can be calculated by Equation 4:

$$I_{DVDD} = C \times V \times f$$

where:

- C = Load capacitance on the SDO line,
- V = DVDD supply voltage, and
- f = Number of transitions on the SDO output. (4)

The number of transitions on the SDO output depends on the output code, and thus changes with the analog input. The maximum value of f occurs when data output on the SDO change on every SCLK. SDO changing on every SCLK results in an output code of AAAh or 555h. For an output code of AAAh or 555h at a 1-MSPS throughput, the frequency of transitions on the SDO output is 6 MHz.

To keep the current consumption at the lowest possible value, the DVDD supply must be kept at the lowest permissible value and the capacitance on the SDO line must be kept as low as possible.

10.3 Optimizing Power Consumed by the Device

- Keep the analog supply voltage (AVDD) as per the analog input full-scale range (FSR) requirement.
- Keep the digital supply voltage (DVDD) at the lowest permissible value.
- Reduce the load capacitance on the SDO output.
- Run the device at optimum throughput. Power consumption reduces with throughput.

11 Layout

11.1 Layout Guidelines

Figure 46 shows a board layout example for the ADS7044. Use a ground plane underneath the device and partition the PCB into analog and digital sections. Avoid crossing digital lines with the analog signal path and keep the analog input signals and the reference input signals away from noise sources. In Figure 46, the analog input and reference signals are routed on the top and left side of the device while the digital connections are routed on the bottom and right side of the device.

The power sources to the device must be clean and well-bypassed. Use 1- μ F ceramic bypass capacitors in close proximity to the analog (AVDD) and digital (DVDD) power-supply pins. Avoid placing vias between the AVDD and DVDD pins and the bypass capacitors. Connect all ground pins to the ground plane using short, low-impedance paths. The AVDD supply voltage for the ADS7044 also functions as a reference for the device. Place the decoupling capacitor (C_{REF}) for AVDD close to the device AVDD and GND pins. C_{REF} must be connected to the device pins with thick copper tracks, as shown in Figure 46.

The fly-wheel RC filters are placed close to the device. Among ceramic surface-mount capacitors, COG (NPO) ceramic capacitors provide the best capacitance precision. The type of dielectric used in COG (NPO) ceramic capacitors provides the most stable electrical properties over voltage, frequency, and temperature changes.

(1) The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

OBSOLETE: TI has discontinued the production of the device.

(2) **RoHS:** TI defines "RoHS" to mean semiconductor products that are compliant with the current EU RoHS requirements for all 10 RoHS substances, including the requirement that RoHS substance do not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, "RoHS" products are suitable for use in specified lead-free processes. TI may reference these types of products as "Pb-Free".

RoHS Exempt: TI defines "RoHS Exempt" to mean products that contain lead but are compliant with EU RoHS pursuant to a specific EU RoHS exemption.

Green: TI defines "Green" to mean the content of Chlorine (Cl) and Bromine (Br) based flame retardants meet JS709B low halogen requirements of <=1000ppm threshold. Antimony trioxide based flame retardants must also meet the <=1000ppm threshold requirement.

(3) MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

(4) There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

(5) Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "-" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

(6) Lead finish/Ball material - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead finish/Ball material values may wrap to two lines if the finish value exceeds the maximum column width.
